membrane disease might affect the COL4A3 and COL4A4 genes too. While carriers of X linked Alport’s syndrome may also have thinned membranes, these have distinctive regions of lamellation, and there is usually a family history of X linked Alport’s syndrome, renal failure, or inherited deafness.

We have confirmed that thin basement membrane disease is linked to the COL4A5/COL4A4 genes in six of 13 affected families (46%). We suspect that more families with thin basement membrane disease also have mutations in these genes, but that we cannot show this because some family members have pathogenic mutations but no haematuria (incomplete penetrance) and because some mutations have arisen in younger family members and are absent from previous generations (de novo mutations). Our results indicate only that thin basement membrane disease is often due to COL4A3 and COL4A4 mutations and not that affected individuals are necessarily carriers of autosomal recessive Alport’s syndrome.

Many studies, as well as the name benign familial haematuria, attest to the generally excellent prognosis of thin basement membrane disease. This condition does not predispose to hypertension or pre-eclampsia, and though some renal impairment is present in 7% of affected individuals are necessarily carriers of auto-

COL4A3 and COL4A4 mutations and not that thin basement membrane disease is often due to COL4A3 and COL4A4 mutations and not that affected individuals are necessarily carriers of autoso-

mal recessive Alport’s syndrome.

In summary, thin basement membrane disease should be suspected when there is lifelong glomerular haematuria, minimal proteinuria, and normal renal function in the absence of a family history of renal failure or deafness that suggests X linked Alport’s syndrome. The diagnosis is confirmed when another family member also has persistent glomerular haematuria. A renal biopsy is warranted only if the diagnosis is unclear, especially if X linked Alport syndrome cannot be excluded or a superimposed glomerulonephritis is suspected. The major differential diagnosis is IgA glomerulonephritis, which is characterised by episodic macroscopic haematuria with intercurrent infections (synpharyngitic haematuria), proteinuria, hypertension, and progressive renal impairment in one third of individuals and no family history of haematuria. In practice, differentiating between thin basement membrane disease and IgA glomerulonephritis is usually not difficult using these clinical features alone.

Effectiveness, efficiency, and NICE

A NICE start but evidence costs money

The National Institute for Clinical Excellence (NICE) was established in England and Wales in 1999 to “provide guidance to the NHS on the use of selected new and established technologies.” NICE synthesises evidence on the effectiveness and cost of treatments and reaches “a judgment as to whether, on balance, the intervention can be recommended as a cost-effective use of NHS resources.” How has the institute measured up to these ambitious goals, and what has been learnt about the demands of an explicit process for assessing health technology?

The institute attracted attention from the international media with its first judgment that “health professionals should not prescribe zanamivir (Relenza) during the 1999/2000 influenza season.” The additional cost to the NHS would have been about £10m ($15m) for the benefit of reducing episodes of flu from six days to five. Although subsequently revised, the decision showed that the institute has teeth and is prepared to bite even home grown drug companies like GlaxoWellcome (now GlaxoSmithKline). In some places, such as Australia and Ontario, Canada, pharmaceutical companies must prove that their products are cost effective before they can be reimbursed by the government. Although NICE operates differently in that it does not automatically assess new products and provides guidance rather than mandates, it is clear

that products will need to be both effective and provide good value for money to be recommended for use in the NHS. Unusually, NICE's remit also includes medical devices and other healthcare programmes, and its activities are surely being scrutinised by other healthcare systems.

But the evidence on which the analyses of costs and benefits are based is often incomplete or inappropriate. The appraisal of hip prostheses, for example, suffered from the dearth of long term data on revision rates. Similarly, the continuing deliberations about interferon beta are likely to be constrained by data from short term trials with outcome measures that are of limited relevance to decisions about the allocation of resources. The institute, however, is pragmatic about any shortfalls in evidence: give the best advice possible using the data available today, but be prepared to revisit judgments when better data arrive. For many technologies—particularly those without a sponsoring company—the onus for generating adequate data will lie with the NHS health technology assessment programme; its budget may need to be increased, but using NHS resources to generate evidence may be money well spent.

The institute's appraisals are likely to have major implications for the drug and medical device industries because these industries supply much of the information for appraisal. The need to submit dossiers in support of their products is making companies think carefully about their research and development programmes. When products have been marketed for some time it is possible for companies routinely to accumulate data, although the data are not typically gathered within the framework of experimental studies. NICE will, however, increasingly have to consider products which have yet to reach the market, so such "real life" data will be lacking. Before launching a new product, drug companies have in the past focused on generating evidence for the drug licensing authorities. Such data are generally of limited value to NICE, so companies are likely to invest in more pragmatic clinical trials with broader population bases to collect the data on cost and health outcomes which are relevant to NICE's decision making.

The institute's interest in finding value for money puts the methods of economic evaluation under the microscope. Although analytical economic methods have developed rapidly, they have yet to make a major impact on applied economic evaluations and on the data submitted to NICE. The institute's recent publication of more detailed guidance for economic data submitted to NICE. The institute's recent impact on applied economic evaluations and on the microscope. Although analytical economic methods put the methods of economic evaluation under the

The rationale for NICE is, in part, based on the desire to end the uneven geographical distribution of particular forms of health care. However, unless funding is earmarked and made available to health authorities for these interventions, they can only be offered to patients if the provision of other services elsewhere in the system is curtailed. Hence, local variations in the availability of particular services will remain; the appraisal process will simply shift the unevenness between services. The institute's role in developing clinical practice guidelines, taken together with national service frameworks, promises to ameliorate this problem. It will be necessary to expand the appraisal process, particularly to identify widely used technologies that are not cost effective, to release resources for new interventions. In principle, NICE's role in looking at a wide range of both new and old technologies is important, although the focus of the latest group of interventions to be appraised is narrow and concentrates largely on new cancer drugs.

The NHS and other healthcare systems that are collectively funded need transparent decision making about which types of health care offer value for money and thus can justifiably be funded; this decision making needs to use appropriate and explicit methods. There is much to commend in the early stages of the institute's appraisal process, not least the openness and transparency it has achieved through its website (www.nice.org.uk). Part of the challenge for NICE and the assessment of health technology in England and Wales is economic: gathering, synthesising, and scrutinising data is a valuable exercise but it is costly. The amount and allocation of research funds should also pass the test of cost effectiveness. This will depend on whether clinicians and managers in the NHS take notice of NICE's guidance.
