1. Let $T$ be a positive random variable denoting the longevity of a randomly selected product, item, or person (such as an ink cartridge, battery, computer, iPod, or human). Denote the associated cumulative distribution function by $F_{T}(t)$, the survival function by $S_{T}(t)=1-F_{T}(t)$, the probability density function by $f_{T}(t)$, and the expectation $\int_{0}^{\infty} f_{T}(t) d t$ by $\mu_{T}$. Show that

$$
\mu_{T}=\int_{0}^{\infty} S_{T}(t) d t
$$

Heuristically: the mean longevity of 82.21 years in Fig. 1 is the total number of person-years $(8221 \mathrm{P}-\mathrm{Y}) \div$ the number of persons $(100)$. The $8221 \mathrm{P}-\mathrm{Y}$ can be seen as the sum of the lengths of the horizontal lines (i.e., first sum the years for the same person, and then sum over persons) or the sum of the lengths of the vertical lines (i.e., first sum the persons for the same year of age, and then sum over years).
2. Consider the 'potential years of life lost' (PYLL) by a woman who dies of cervical cancer at age 45 , i.e., the additional years she could have expected to live had she been protected against this cancer. Because the equation in (ii) may not be valid beyond 85, use the life-span 45-85 for both (i) and (ii).

Calculate (a) the (conditional) probability that a woman who reaches her 45 th birthday will be alive on her 85 th birthday, and (b) the expected (mean) number of additional years that women who reach 45 will live over the next 40 years. Determine (a) and (b) in 2 ways, based on the...
i. 2000-2002 (Current) Complete Life-table, Canadian Females (next pages)
ii. hazard rate / mortality rate / incidence density function ${ }^{1}$, $h($ age $)$, fitted to the observed age-specific all-cause mortality rates for Québec women aged 45-85 in 2002:

$$
\log h(\text { age })=-6.7+0.10 \times(\text { age }-45) . \text { see footnote }{ }^{2}
$$

3. Calculate the not-for-profit ${ }^{3} 1$-year life-insurance premium for
i. a Canadian woman aged 50, in "average" health, based on the 2000-2002 (Current) Complete Life-table for Canadian females;
ii. a Québec woman aged 50, in "average" health, based on the fitted hazard function given above.

[^0]

Figure 1: 8221 years lived by 100 persons

Note: Estimates with a coefficient of variation (cv) greater than $33.3 \%$ are to be used with caution
$F$ too unreliable to be published (indicates a cv of at least 100.0\%).

[^0]:    ${ }^{1}$ Gompertz (1779-1865) observed in 1825 that the force (intensity, $I$ ) of mortality at age $a$ had the form $I_{0} \beta^{a}$ over a wide age-span i.e., age-specific death rates were log-linear-in-age (Gompertz 'Law of Mortality'). Random variables whose hazard functions follow this form are said to follow the Gompertz Distribution.
    ${ }^{2}$ Integral of this has closed form; or, could use num'l integration, e.g. integrate in R
    ${ }^{3}$ Such that in a large number of such insured persons, the premiums collected would just balance the total amount of the death benefits (each one valued at $\$ 10,000$ ) paid out.
